### Features

- Compatible with MCS-51<sup>™</sup> Products
- 1K Bytes of Reprogrammable Flash Memory – Endurance: 1,000 Write/Erase Cycles
- 2.7V to 6V Operating Range
- Fully Static Operation: 0 Hz to 24 MHz
- Two-level Program Memory Lock
- 64 x 8-bit Internal RAM
- 15 Programmable I/O Lines
- Two 16-bit Timer/Counters
- Six Interrupt Sources
- Programmable Serial UART Channel
- Direct LED Drive Outputs
- On-chip Analog Comparator
- Low-power Idle and Power-down Modes

### Description

The AT89C1051U is a low-voltage, high-performance CMOS 8-bit microcomputer with 1K byte of Flash programmable and erasable read only memory. It has the same functionality and operation as the AT89C1051 with the addition of a UART programmable serial port. The device is manufactured using Atmel's high-density nonvolatile memory technology and is compatible with the industry-standard MCS-51 instruction set. By combining a versatile 8-bit CPU with Flash on a monolithic chip, the Atmel AT89C1051U is a powerful microcomputer which provides a highly-flexible and cost-effective solution to many embedded control applications.

The AT89C1051U provides the following standard features: 1K byte of Flash, 64 bytes of RAM, 15 I/O lines, two 16-bit timer/counters, a five-vector, two-level interrupt architecture, a full duplex serial port, a precision analog comparator, on-chip oscillator and clock circuitry. In addition, the AT89C1051U is designed with static logic for operation down to zero frequency and supports two software-selectable power saving modes. The Idle Mode stops the CPU while allowing the RAM, timer/counters, serial port and interrupt system to continue functioning. The power-down mode saves the RAM contents but freezes the oscillator disabling all other chip functions until the next hardware reset.

## AT89C1051U

Rev. 1045C-02/00

### **Block Diagram**

AT89C1051U

### **Pin Description**

#### vcc

Supply voltage.

#### GND

Ground.

#### Port 1

Port 1 is an 8-bit bidirectional I/O port. Port pins P1.2 to P1.7 provide internal pullups. P1.0 and P1.1 require external pullups. P1.0 and P1.1 also serve as the positive input (AIN0) and the negative input (AIN1), respectively, of the on-chip precision analog comparator. The Port 1 output buffers can sink 20 mA and can drive LED displays directly. When 1s are written to Port 1 pins, they can be used as inputs. When pins P1.2 to P1.7 are used as inputs and are externally pulled low, they will source current ( $I_{IL}$ ) because of the internal pullups.

Port 1 also receives code data during Flash programming and verification.

#### Port 3

Port 3 pins P3.0 to P3.5, P3.7 are seven bidirectional I/O pins with internal pullups. P3.6 is hard-wired as an input to the output of the on-chip comparator and is not accessible as a general purpose I/O pin. The Port 3 output buffers can sink 20 mA. When 1s are written to Port 3 pins they are pulled high by the internal pullups and can be used as inputs. As inputs, Port 3 pins that are externally being pulled low will source current ( $I_{\rm IL}$ ) because of the pullups.

Port 3 also serves the functions of various special features of the AT89C1051U as listed below:

Port Pin	Alternate Functions
P3.0	RXD (serial input port)
P3.1	TXD (serial output port)
P3.2	INTO (external interrupt 0)
P3.3	INT1 (external interrupt 1)
P3.4	T0 (timer 0 external input)
P3.5	T1 (timer 1 external input)

Port 3 also receives some control signals for Flash programming and verification.

#### RST

Reset input. All I/O pins are reset to 1s as soon as RST goes high. Holding the RST pin high for two machine cycles while the oscillator is running resets the device.

Each machine cycle takes 12 oscillator or clock cycles.

#### XTAL1

Input to the inverting oscillator amplifier and input to the internal clock operating circuit.

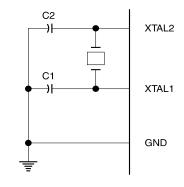

#### XTAL2

Output from the inverting oscillator amplifier.

### **Oscillator Characteristics**

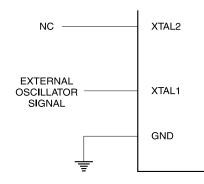

XTAL1 and XTAL2 are the input and output, respectively, of an inverting amplifier which can be configured for use as an on-chip oscillator, as shown in Figure 1. Either a quartz crystal or ceramic resonator may be used. To drive the device from an external clock source, XTAL2 should be left unconnected while XTAL1 is driven as shown in Figure 2. There are no requirements on the duty cycle of the external clock signal, since the input to the internal clocking circuitry is through a divide-by-two flip-flop, but minimum and maximum voltage high and low time specifications must be observed.

Note: C1, C2= 30 pF  $\pm$  10 pF for Crystals = 40 pF  $\pm$  10 pF for Ceramic Resonators

**Special Function Registers** A map of the on-chip memory area called the Special Function Register (SFR) space is shown in the table below. Note that not all of the addresses are occupied, and unoc-

Note that not all of the addresses are occupied, and unoccupied addresses may not be implemented on the chip. Read accesses to these addresses will in general return random data, and write accesses will have an indeterminate effect. User software should not write 1s to these unlisted locations, since they may be used in future products to invoke new features. In that case, the reset or inactive values of the new bits will always be 0.

### **Restrictions on Certain Instructions**

The AT89C1051U and is an economical and cost-effective member of Atmel's growing family of microcontrollers. It contains 1K byte of flash program memory. It is fully compatible with the MCS-51 architecture, and can be programmed using the MCS-51 instruction set. However, there are a few considerations one must keep in mind when utilizing certain instructions to program this device.

All the instructions related to jumping or branching should be restricted such that the destination address falls within the physical program memory space of the device, which is 1K for the AT89C1051U. This should be the responsibility of the software programmer. For example, LJMP 3FEH would be a valid instruction for the AT89C1051U (with 1K of memory), whereas LJMP 410H would not.

#### 1. Branching instructions:

LCALL, LJMP, ACALL, AJMP, SJMP, JMP @A+DPTR.

These unconditional branching instructions will execute correctly as long as the programmer keeps in mind that the destination branching address must fall within the physical boundaries of the program memory size (locations 00H to 3FFH for the 89C1051U). Violating the physical space limits may cause unknown program behavior.

CJNE [...], DJNZ [...], JB, JNB, JC, JNC, JBC, JZ, JNZ With these conditional branching instructions the same rule above applies. Again, violating the memory boundaries may cause erratic execution.

For applications involving interrupts the normal interrupt service routine address locations of the 80C51 family architecture have been preserved.

#### 2. MOVX-related instructions, Data Memory:

The AT89C1051U contains 64 bytes of internal data memory. Thus, in the AT89C1051U the stack depth is limited to 64 bytes, the amount of available RAM. External DATA memory access is not supported in this device, nor is external PROGRAM memory execution. Therefore, no MOVX [...] instructions should be included in the program.

A typical 80C51 assembler will still assemble instructions, even if they are written in violation of the restrictions mentioned above. It is the responsibility of the controller user to know the physical features and limitations of the device being used and adjust the instructions used correspondingly.

### Programmable Serial UART Channel<sup>(1)</sup>

The AT89C1051U offers a programmable serial port which is compatible with the serial ports on other AT89 series flash MCU products. A detailed description of the serial port operation can be found in the Hardware Description section of the Atmel AT89 series flash MCU data book.

Note: 1. This feature is not available on the AT89C1051.

### **Program Memory Lock Bits**

On the chip are two lock bits which can be left unprogrammed (U) or can be programmed (P) to obtain the additional features listed in the table below:

#### Lock Bit Protection Modes<sup>(1)</sup>

Prog	Program Lock Bits		
	LB1	LB2	Protection Type
1	U	U	No program lock features.
2	Р	U	Further programming of the Flash is disabled.
3	Р	Р	Same as mode 2, also verify is disabled.

Note: 1. The Lock Bits can only be erased with the Chip Erase operation.

#### Idle Mode

In idle mode, the CPU puts itself to sleep while all the onchip peripherals remain active. The mode is invoked by software. The content of the on-chip RAM and all the special functions registers remain unchanged during this mode. The idle mode can be terminated by any enabled interrupt or by a hardware reset.

P1.0 and P1.1 should be set to "0" if no external pullups are used, or set to "1" if external pullups are used.

It should be noted that when idle is terminated by a hardware reset, the device normally resumes program execution, from where it left off, up to two machine cycles before the internal reset algorithm takes control. On-chip hardware inhibits access to internal RAM in this event, but access to the port pins is not inhibited. To eliminate the possibility of an unexpected write to a port pin when Idle is terminated by reset, the instruction following the one that invokes Idle should not be one that writes to a port pin or to external memory.

#### **Power-down Mode**

In the power-down mode the oscillator is stopped, and the instruction that invokes power-down is the last instruction executed. The on-chip RAM and Special Function Registers retain their values until the power-down mode is terminated. The only exit from power-down is a hardware reset. Reset redefines the SFRs but does not change the on-chip RAM. The reset should not be activated before  $V_{CC}$ 

is restored to its normal operating level and must be held active long enough to allow the oscillator to restart and stabilize.

P1.0 and P1.1 should be set to "0" if no external pullups are used, or set to "1" if external pullups are used.

### **Programming The Flash**

The AT89C1051U is shipped with the 1K byte of on-chip PEROM code memory array in the erased state (i.e., contents = FFH) and ready to be programmed. The code memory array is programmed one byte at a time. Once the array is programmed, to re-program any non-blank byte, the entire memory array needs to be erased electrically.

**Internal Address Counter:** The AT89C1051U contains an internal PEROM address counter which is always reset to 000H on the rising edge of RST and is advanced by applying a positive going pulse to pin XTAL1.

**Programming Algorithm:** To program the AT89C1051U, the following sequence is recommended.

- Power-up sequence: Apply power between V<sub>CC</sub> and GND pins Set RST and XTAL1 to GND
- 2. Set pin RST to "H" Set pin P3.2 to "H"
- 3. Apply the appropriate combination of "H" or "L" logic levels to pins P3.3, P3.4, P3.5, P3.7 to select one of the programming operations shown in the PEROM Programming Modes table.

To Program and Verify the Array:

- 4. Apply data for Code byte at location 000H to P1.0 to P1.7.
- 5. Raise RST to 12V to enable programming.
- 6. Pulse P3.2 once to program a byte in the PEROM array or the lock bits. The byte-write cycle is self-timed and typically takes 1.2 ms.
- To verify the programmed data, lower RST from 12V to logic "H" level and set pins P3.3 to P3.7 to the appropriate levels. Output data can be read at the port P1 pins.
- 8. To program a byte at the next address location, pulse XTAL1 pin once to advance the internal address counter. Apply new data to the port P1 pins.
- 9. Repeat steps 5 through 8, changing data and advancing the address counter for the entire 1K byte array or until the end of the object file is reached.
- 10. Power-off sequence: set XTAL1 to "L" set RST to "L" Turn V<sub>CC</sub> power off

**Data Polling:** The AT89C1051U features Data Polling to indicate the end of a write cycle. During a write cycle, an attempted read of the last byte written will result in the complement of the written data on P1.7. Once the write cycle has been completed, true data is valid on all outputs, and the next cycle may begin. Data Polling may begin any time after a write cycle has been initiated.

**Ready/Busy:** The Progress of byte programming can also be monitored by the RDY/BSY output signal. Pin P3.1 is pulled low after P3.2 goes High during programming to indicate BUSY. P3.1 is pulled High again when programming is done to indicate READY.

**Program Verify:** If lock bits LB1 and LB2 have not been programmed code data can be read back via the data lines for verification:

- 1. Reset the internal address counter to 000H by bringing RST from "L" to "H".
- 2. Apply the appropriate control signals for Read Code data and read the output data at the port P1 pins.
- 3. Pulse pin XTAL1 once to advance the internal address counter.
- 4. Read the next code data byte at the port P1 pins.
- 5. Repeat steps 3 and 4 until the entire array is read.

The lock bits cannot be verified directly. Verification of the lock bits is achieved by observing that their features are enabled.

**Chip Erase:** The entire PEROM array (1K byte) and the two Lock Bits are erased electrically by using the proper combination of control signals and by holding P3.2 low for 10 ms. The code array is written with all "1"s in the Chip Erase operation and must be executed before any nonblank memory byte can be re-programmed.

**Reading the Signature Bytes:** The signature bytes are read by the same procedure as a normal verification of locations 000H, 001H, and 002H, except that P3.5 and P3.7 must be pulled to a logic low. The values returned are as follows.

(000H) = 1EH indicates manufactured by Atmel (001H) = 12H indicates 89C1051U

### **Programming Interface**

Every code byte in the Flash array can be written and the entire array can be erased by using the appropriate combination of control signals. The write operation cycle is selftimed and once initiated, will automatically time itself to completion.

All major programming vendors offer worldwide support for the Atmel microcontroller series. Please contact your local programming vendor for the appropriate software revision.

### **Flash Programming Modes**

Mode		RST/VPP	P3.2/PROG	P3.3	P3.4	P3.5	P3.7
Write Code Data <sup>(1)(3)</sup>		12V	~	L	Н	Н	Н
Read Code Data <sup>(1)</sup>		н	Н	L	L	н	Н
Write Lock	Bit - 1	12V	~	Н	Н	Н	Н
	Bit - 2	12V	~	Н	Н	L	L
Chip Erase	1	12V	(2)	Н	L	L	L
Read Signature Byte		Н	Н	L	L	L	L

Notes: 1. The internal PEROM address counter is reset to 000H on the rising edge of RST and is advanced by a positive pulse at XTAL1 pin.

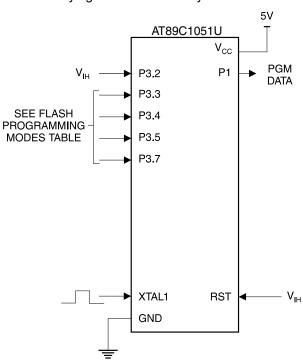

2. Chip Erase requires a 10-ms  $\overline{\text{PROG}}$  pulse.

3. P3.1 is pulled Low during programming to indicate RDY/BSY.

Notes: 1. Under steady state (non-transient) conditions, I<sub>OL</sub> must be externally limited as follows:

Maximum I<sub>OL</sub> per port pin: 20 mA

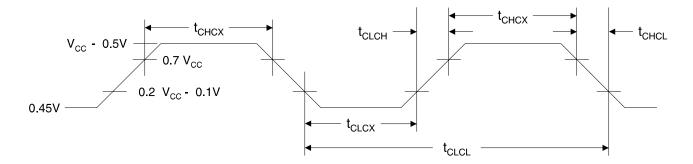

Maximum total  $I_{OL}$  for all output pins: 80 mA If  $I_{OL}$  exceeds the test condition,  $V_{OL}$  may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.

2. Minimum  $V_{CC}$  for Power-down is 2V.

### **External Clock Drive Waveforms**

#### **External Clock Drive**

		V <sub>CC</sub> = 2.	7V to 6.0V	V <sub>CC</sub> = 4.0	)V to 6.0V	
Symbol	Parameter	Min	Max	Min	Max	Units

t <sub>XHDX</sub>	Input Data Hold after Clock Rising Edge	0		0		ns
t <sub>XHDV</sub>	Clock Rising Edge to Input Data Valid		700		10t <sub>CLCL</sub> -133	ns

 $V_{CC} = 5.0V \pm 20\%$ ; Load Capacitance = 80 pF

### Shift Register Mode Timing Waveforms

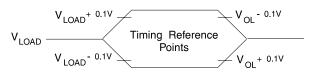

### AC Testing Input/Output Waveforms<sup>(1)</sup>

#### Float Waveforms<sup>(1)</sup>

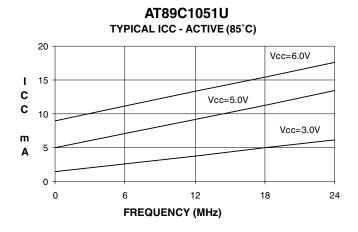

Note: 1. AC Inputs during testing are driven at  $V_{CC}$  - 0.5V for a logic 1 and 0.45V for a logic 0. Timing measurements are made at  $V_{IH}$  min. for a logic 1 and  $V_{IL}$  max. for a logic 0.

Note: 1. For timing purposes, a port pin is no longer floating when a 100 mV change from load voltage occurs. A port pin begins to float when 100 mV change from the loaded V<sub>OH</sub>/V<sub>OL</sub> level occurs.
